

Schaft Creek Bird Studies Baseline Report 2006

Prepared by:

Rescan Tahltan Environmental Consultants
Vancouver, British Columbia

May 2007

EXECUTIVE SUMMARY

Executive Summary

CopperFox Metals Inc. (CopperFox) has begun an initiative to develop a copper-gold-molybdenum-silver project within the Schaft Creek watershed approximately 140 km southwest of Dease Lake in north-western British Columbia. Identification of avian species in the area is an important initial step prior to suggesting mitigation measures to meet the obligations of federal and provincial standards for species protection. Avifauna that reside in the area or which migrate to the area in order to breed could potentially be affected by development, depending on the species present, their habitat requirements, and their local, regional, and National status. If rare species are identified in the area, they may also be protected by provincial and Federal regulations such as the B.C. Wildlife Act, Migratory Bird Convention Act, and Species at Risk Act (SARA).

This report summarizes the 2006 bird study baseline inventory within the Schaft Creek Project area. The avian field plan was designed to maximize the potential for detecting a wide range of species and to characterize the distribution and habitat associations of waterfowl and riverine birds (particularly harlequin ducks), raptors and breeding songbirds. Baseline surveys were conducted in the study area associated with the development footprint and within 1 km of the proposed access corridor.

Waterfowl and Riverine Birds

Aerial surveys were conducted for riverine birds, harlequin duck (*Histrionicus histrionicus*), and other waterfowl during spring (May) and summer (July/August) 2006 within the study area. The goal of these surveys was to characterize waterfowl and riverine bird diversity and to identify habitats used for migration staging and breeding in the study area. A total of 21 species of waterfowl were observed within the study area, including six dabbling species, nine species of diver, two species of geese, two species of loons, trumpeter swans (*Cygnus buccinator*), and eared grebes (*Podiceps nigricollis*). During spring, the distribution of waterfowl was relatively uniform among reaches, although higher concentrations existed, particularly within the larger wetland complexes associated with Schaft Creek and upper Mess Creek.

During the summer breeding survey, 22 broods of seven species were detected including, green winged-teal (*Anas crecca*), mallard (*Anas platyrhynchos*), Barrow's goldeneye (*Bucephala islandica*), lesser scaup (*Aythya affinis*), ring-necked duck (*Aythya collaris*), bufflehead (*Becephala alboeola*) and unidentified scoter (*Melanitta spp.*) species. The distribution of waterfowl brood observations was relatively similar throughout the study area. Upper Mess Creek support broods of dabblers, divers and geese, whereas, other areas supported broods of dabblers (Schaft Creek), divers (tributaries of Schaft and Mess creeks), or both (lower Mess Creek).

Harlequin duck pairs were mostly observed within the tributaries of Schaft and Mess creeks within the study area. The forested riparian habitat combined with the stream geomorphology of the tributaries likely provided habitat more conducive to harlequin breeding and thus these reaches were selected in spring. An average density of 0.15 harlequin ducks/km was observed over the entire search area during spring. No harlequin duck broods were observed during the

Executive Summary

July/August breeding survey. The apparent lack of productivity may be a product of the late spring in 2006, combined with the cryptic nature of the young broods, than a lack of use of this habitat for breeding. Harlequin ducks nest near areas of pair activity, and as such, the reaches in the study area where pairs were observed are likely to be important for nesting and brood rearing by harlequin ducks.

Raptors

Call playback surveys for northern goshawk (*Accipiter gentilis*) were conducted in June 2006 along the proposed access corridor and within the mine site footprint. One northern goshawk was identified along Mess Creek. Observers believed that this individual was unlikely to be of the *laingi* subspecies, and therefore not a species at risk.

Stand watch surveys for tree and cliff nesting raptors were conducted in June 2006. These surveys combined with incidental observations detected eight additional raptor species within the study area: American kestrel (*Falco sparverius*), bald eagle (*Haliaeetus leucocephalus*), golden eagle (*Aquila chrysaetos*), merlin (*Falco columbarius*), northern harrier (*Circus cyaneus*), osprey (*Pandion haliaetus*), red-tailed hawk (*Buteo jamaicensis*) and sharp-shinned hawk (*Accipiter striatus*). Of these, breeding was confirmed for two species: osprey and bald eagle. Three active osprey nests were observed along upper Mess Creek during stand watch surveys and one bald eagle nest with 3 eggs was incidentally observed along Schaft Creek during waterfowl surveys.

Songbirds

There was a moderately high diversity of breeding songbirds (61 species) identified in the proposed access corridor, with high variation in species numbers and diversity between variable radius point count (VRPC) plots. The highest species diversity and abundance of birds was found within low-elevation forest and riparian marshland transitional habitat along upper Mess Creek adjacent to the proposed access corridor. Higher elevation sites above the treeline with predominantly rocky substrata hosted a low abundance and diversity of breeding songbirds. One songbird species of concern (COSEWIC, provincially Blue-listed), the rusty blackbird (*Euphagus carolinus*), was identified within the study area.

ACKNOWLEDGEMENTS

Acknowledgements

This report was prepared for CopperFox Metals Inc. by Rescan Environmental Services Ltd. The project was managed by Shane Uren (M.A.Sc., R.P.Bio.) of Rescan. The report was written by Shaun Freeman (B.Sc., R.P.Bio.) and Heather Bears (M.Sc., Ph.D.), and edited by Brandie Harding (B.Sc.). Fieldwork was conducted by Guy Monty, with assistance from James Malone. Accommodation was provided by CopperFox Metals Ltd. at the Schaft Creek Camp and helicopter support was provided by Pacific Western Helicopters. Report production was coordinated by Amanda Broda.

1. INTRODUCTION

1. Introduction

CopperFox Metals Inc. (CopperFox) has initiated a project to develop a copper-gold-molybdenum-silver property within the Schaft Creek drainage in north-western British Columbia. Initial plans for the project include constructing a site access through Mess Creek that will connect to the transportation corridor of the Galore Creek project to the south. The availability of pristine habitat for wildlife use within the area may be affected by the development and accurate data of major wildlife groups that potentially use the area requires investigation and consideration. Avifauna that reside in the area or which migrate to the area in order to breed could potentially be affected by development depending on species present, their habitat requirements, and their local, regional and National status.

Identification of avian species in the area is an important initial step prior to suggesting mitigation measures to meet the obligations of federal and provincial standards for species protection. Birds are an important group for consideration of wildlife impacts throughout the planning, implementation, and post-development monitoring of a development for a number of reasons. Waterfowl are valued socially and economically by many communities across North America. Harlequin duck (*Histrionicus histrionicus*), for example, is of particular interest to federal regulators as it occupies a unique habitat niche and has received widespread concern following declines in Pacific populations. Avian species that migrate between countries also represent one of the few wildlife groups that receive international pressure for species conservation, and this group requires consideration for statutory obligations as under the federal Migratory Bird Convention Act. Raptors may also exist in the area, which are afforded additional protection under the provincial Wildlife Act. Finally, when species at risk are identified in an area, they are protected under the federal Species at Risk Act (SARA).

Prior to the initiation of this investigation, no avian surveys existed within the study area. Hence, initial baseline information was required to identify the birds using the area of the proposed development, and the extent of their use of the study area. This report summarises the baseline inventory conducted in 2006, which characterizes bird communities in the area of the proposed development. The baseline inventory included waterfowl, riverine birds (including shorebirds), raptors, and breeding upland birds (*i.e.*, songbirds).

1.1 Objectives

Avian studies were completed in 2006 with the overall objective of collecting baseline information on species presence and distribution within the Schaft Creek study area. Studies included the assessment of the presence and distribution of bird species of conservation concern (*i.e.*, those species with a provincial red or blue listing, or those listed by the Committee on the Status of Endangered Wildlife in Canada [COSEWIC] as endangered, threatened or special concern), or those species that regulators requested to receive enhanced consideration. The bird studies field plan for 2006 was also designed to maximize the potential for detecting a wide range of species which may exist within the study area. A broad level characterization of

Introduction

regional avian biodiversity was conducted because regional information is generally limited for this somewhat remote and little studied area.

The specific objectives of the 2006 studies were to:

- identify species at risk or of concern (*i.e.*, focal species) potentially occurring within the study area;
- characterize waterfowl biodiversity, distribution and extent of use within the study area;
- determine presence and distribution of riverine birds, with special emphasis on harlequin ducks;
- identify habitats and locations of greatest importance to breeding waterfowl and riverine birds;
- characterize raptor biodiversity, and identify nests of cliff and tree nesting raptors along the proposed access option and within the mine site area that may be directly impacted by the development;
- identify the presence and distribution of raptors occupying riverine and wetland habitats, including eagles, within the study area;
- characterize songbird biodiversity within the major ecosystems that exist within the study area; and
- record important incidental observations of birds, amphibians, and other wildlife encountered in the course of field investigations.

To meet these objectives six survey techniques were employed during the 2006 field season, including:

1. Waterfowl surveys at wetlands within 1 km of the proposed access option and within the mine site development area. This data is required to determine both species and numbers of staging waterfowl, as well as types of habitat used.
2. Aerial surveys for riverine birds with special emphasis on harlequin ducks. Survey effort was directed at rivers within 1 km of the proposed access option and within the mine site development area.
3. Call playback surveys for northern goshawk (*Accipiter gentilis*) in each of the main habitat types occurring within the study area, including the proposed access option and suitable habitat within the mine site area.
4. Stand watches directed at identifying the presence of breeding cliff dwelling raptors with emphasis on listed species including gyrfalcon (*Falco rusticolus*) and peregrine falcon (*Falco peregrinus*).
5. Breeding bird surveys with variable radius point counts (VRPC) at fixed locations within each of the main habitat types occurring within the study area. Surveys focused on sites within 1 km of the proposed access option and within the mine site development area.
6. Record incidental wildlife observations.

1.2 Study Area

The study area included both the area most likely to be associated with the development footprint and the area within 1 km of the proposed access corridor along the upper portion of Mess Creek (Figure 1.2-1). This area was representative of the Mess Creek watershed, and included Schaft Creek and larger tributaries (*i.e.* Walkout Creek, Hickman Creek, *etc.*). The area surveyed included a number of riverine systems, wetlands, forested areas, and alpine tundra. The study area also included a unique transition from coastal to inland ecosystems. The transition is exceptionally pronounced, with relatively gentle and rolling topography east of Mess Creek strongly influenced by the historic volcanic activity that created the Big Raven and Arctic Lake plateaus. The area to the west, by contrast, is extremely rugged with steep, rocky mountains exceeding 2,000 m in elevation and with expansive glaciers.

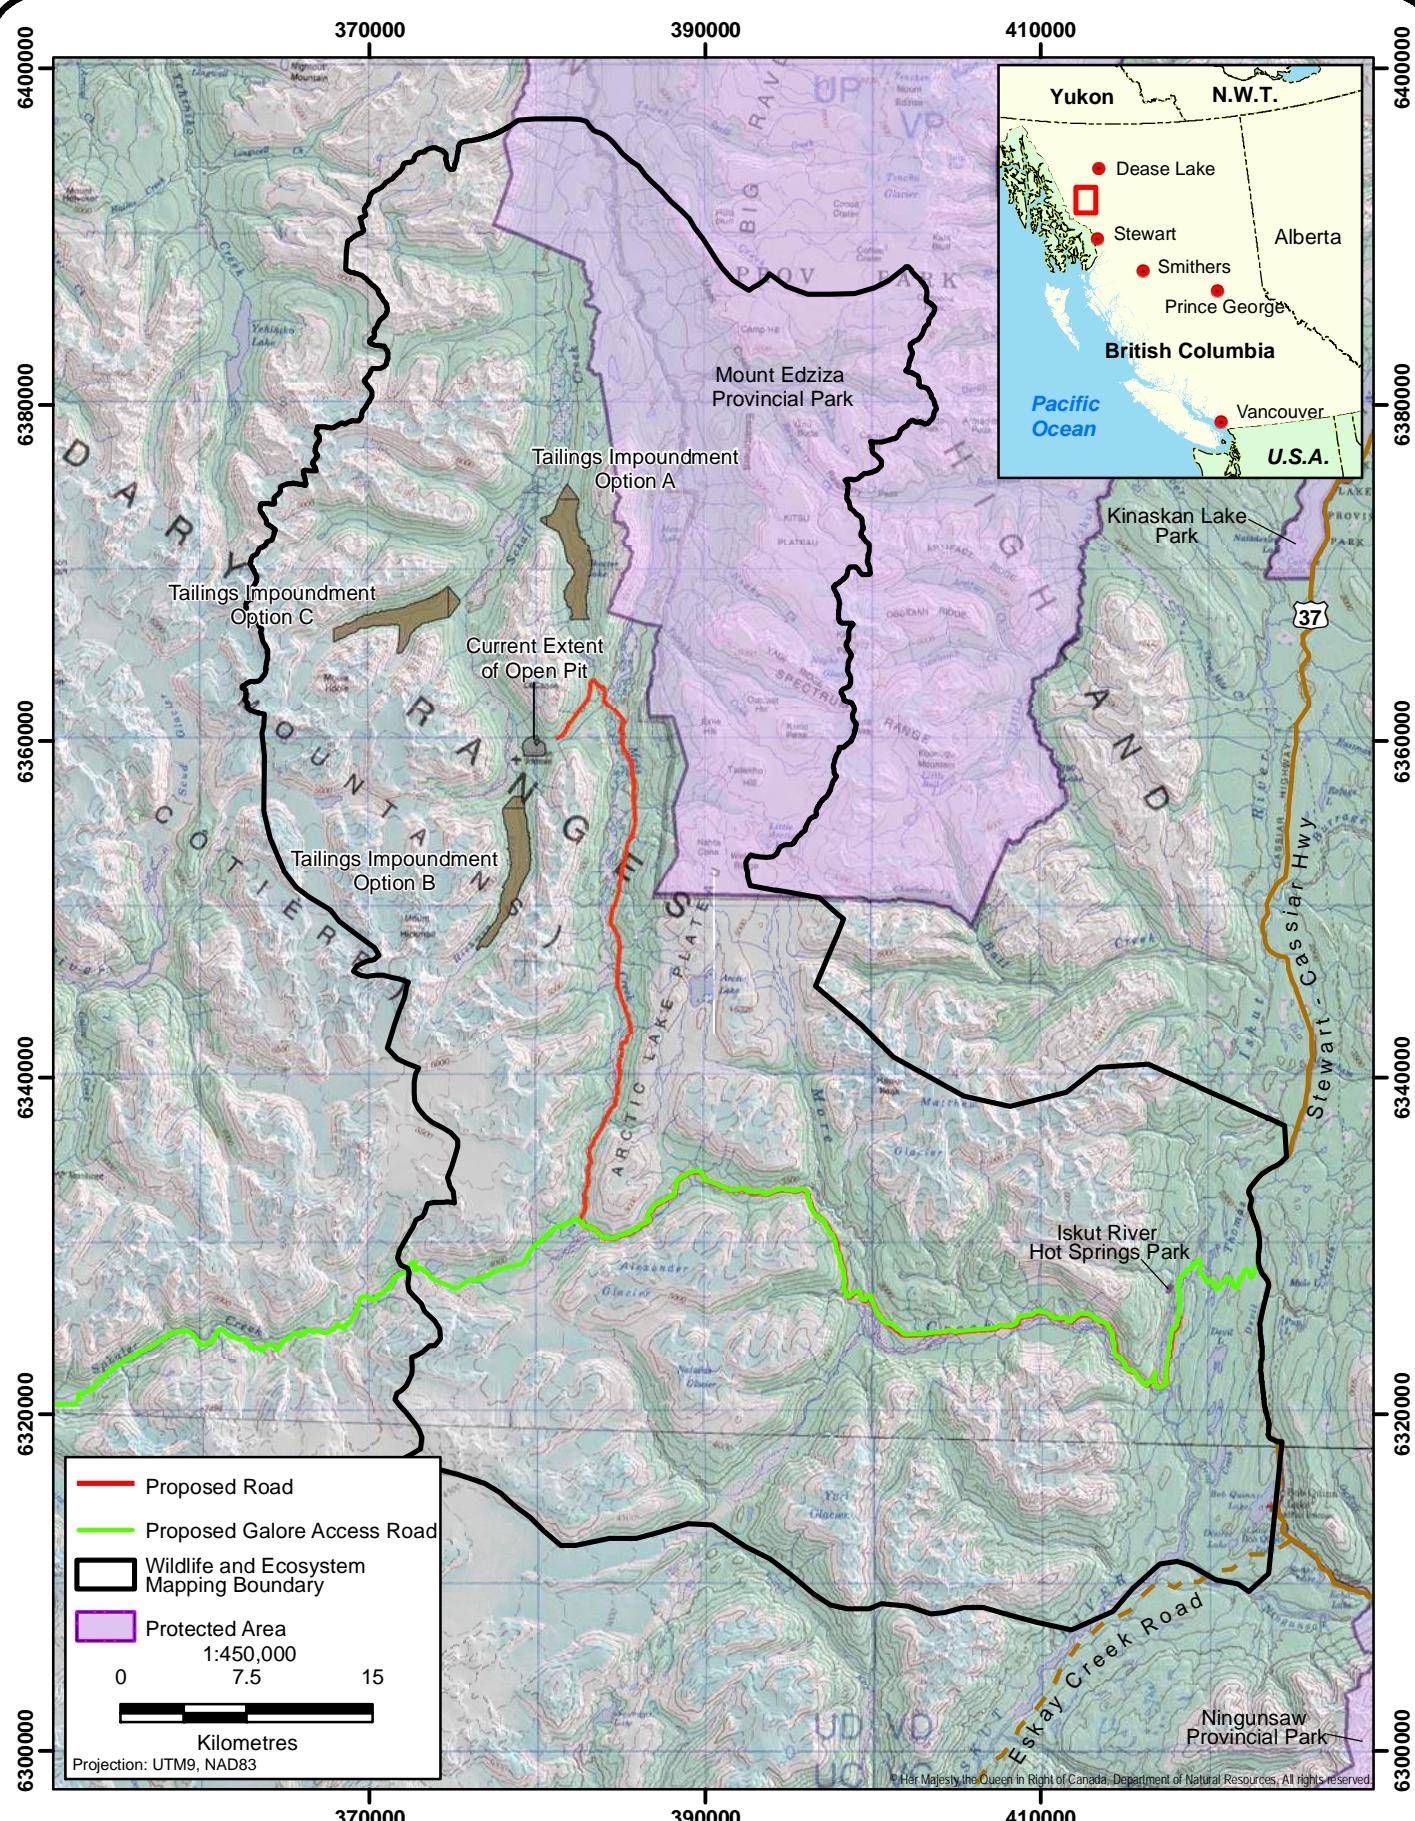

The majority of the study area is representative of the Northern Boreal Mountain ecoprovince, including the Yukon-Stikine Highlands and Northern Mountains and Plateaus ecoregions. Two ecosections occur in the study area, Tahltan Highlands and Southern Boreal Plateau (Luttermerding *et al.*, 1990). The biogeoclimatic ecosystem classification (BEC) system categorizes the study area into the Boreal Altai Fescue Alpine (BAFA), multiple subzones of the Engelmann Spruce-Subalpine Fir (ESSF), Spruce Willow Birch (SWB), and the Boreal White and Black Spruce (BWBS).

The study area currently lacks road access, although past mineral exploration has resulted in some modification to the watersheds. Guided outfitting, recreational hunting, and fur harvest is ongoing in the study area. The north-east portion of the watershed is representative of Mount Edziza Provincial Park, and supports wilderness back country recreation and associated activities.

1.3 Previous Wildlife Studies

Although no prior avian inventory work has been conducted within the area investigated, bird inventories have been conducted in prior projects in areas associated with the upper Mess Creek and More Creek access corridor. These inventories were summarized by Rescan Environmental Services (2006), which identified 61 species of terrestrial breeding birds, 20 species of waterfowl, and 10 species of raptors within the area to the south. Some work was also conducted in the early 1980s along the lower portions of the Mess Creek drainage and the Stikine for the proposed hydro-electric project on the river (Blood and Anweiler, 1982).

A summary of bird species at risk and species of concern that could potentially exist within the study area was compiled from information available from nearby projects, and from the BC Conservation Data Centre (BC CDC 2006). This list suggests that as many as 20 species at risk could potentially be present in the study area (Appendix 1). Rescan Environmental Services (2006) identified four species at risk including, great blue heron (*Ardea herodias*), surf scoter (*Melanitta perspicillata*), gyrfalcon, and peregrine falcon in the Galore Creek study area to the south.

2. WATERFOWL AND RIVERINE BIRDS

2. Waterfowl and Riverine Birds

Aerial surveys were conducted for waterfowl and riverine birds during spring and summer 2006 within the study area. Spring and summer surveys were conducted to characterize waterfowl and riverine bird diversity and to identify habitats used for migration staging and breeding in the study area.

Harlequin duck was identified as a focal species of riverine bird requiring increased consideration for the Project. This species nests near fast flowing rivers and mountain streams (Campbell *et al.*, 1990). Riverine bird survey effort was therefore primarily directed towards this species.

2.1 Methods

Inventories for riverine birds, harlequin ducks, and other waterfowl included pair surveys in May 2006 and then subsequent brood surveys in July and August, 2006. Aerial surveys were conducted using a Bell 206 helicopter with bubble windows occupied by a navigator and observer in addition to the pilot. This methodology was consistent with Resource Inventory Standards Committee (RISC) protocols (RIC, 1999a; RIC, 1998). The helicopter flew at speeds of approximately 60 km/h, and at height of approximately 30 m above the water. Waterfowl were identified using binoculars from the air. On occasions when large numbers of birds were encountered, surveyors were set down on the ground and used a 60x spotting scope to count and identify waterfowl. A hand-held Global Positioning System (GPS) equipped with a remote antenna was used to record survey routes and observation waypoints. These data were downloaded after the survey for use with a Geographic Information System (GIS) platform. Whenever possible, all of the following information was recorded: species, sex, number of birds, and habitat type.

2.1.1 Spring Pair Survey

A spring survey for waterfowl pairs and focused surveys for harlequin ducks was conducted during May 2006. The initial timing of surveys for harlequin ducks was chosen to correspond to peak times for inventory within the nearest available area with data (southern BC; Freeman and Goudie, 1996; Freeman and Goudie, 2001) and from observations made during the 2005 inventory of streams associated with the lower Iskut and Stikine watersheds (Rescan Environmental Services, 2006). Survey dates also spanned arrival times through the breeding period for harlequin ducks in western North America (Robertson and Goudie, 1999).

In early May of 2006, Rescan conducted harlequin duck surveys for four projects within the region, including a re-survey of More and Sphaler Creek areas (Rescan Environmental Services, *unpublished data*). Spring conditions were delayed in 2006 compared to 2005, which resulted in deeper, persistent snow packs and extensive portions of watersheds remaining frozen during the early May 2006 surveys. Open water on streams and rivers supported waterfowl, but much of the higher quality harlequin duck breeding habitat associated with the upper reaches of watersheds was unavailable throughout the region. Therefore, additional survey effort was conducted in the third week of May to map the distribution of harlequin ducks from pair observations. Duplicate surveys of some reaches were conducted.

Analysis of pair survey data included identifying waterfowl use along specific reaches of the watersheds that may be affected by development, and identification of use of general habitat types available. The access corridor and development sites were divided into four main sections representative of similar wetland ecology:

1. Schaft Creek drainage including Hickman Creek (50.0 km length);
2. lower Mess Creek from Elwyn Creek to Mess Lake (40.1 km);
3. upper Mess Creek from Mess Lake to its headwaters (31.9 km); and
4. associated tributaries of the Schaft and Mess Creeks (combined 66.8 km).

General habitat types including River-riffle (Ri-rf), River-glide (Ri-gl), Creek-riffle (CR-rf), Creek-glide (CR-gl), Pond (PO), Lake (LK), Bog (BO), and Marsh (MA) were assessed for waterfowl abundance. Rivers were defined as streams greater than 4 m wet width, while creeks had widths of less than 4 m. Ponds were defined as shallow water bodies with organic substrate and substantial emergent vegetation, while lakes were deeper with predominantly mineral soil substrata. Marshes were areas of shallow water, dominated by rush (*Scirpus* spp.) and sedge (*Carex* spp.) vegetation. For general analysis, waterfowl were classified as Dabbling Ducks, Diving Ducks (including sea ducks), Geese, Swans, Waterbirds (includes loons and grebes), Shorebirds (for the purpose of this report, includes all wading birds and American dipper), and Other (e.g., gulls, raptors, terns, etc.).

2.1.2 Summer Brood Survey

The areas surveyed in spring were again surveyed for broods in the summer to gather direct evidence of breeding in the area. Summer brood surveys were conducted in conjunction with mountain ungulate surveys during July and August, 2006. Data collected during brood surveys included species, number, and sex whenever possible. Brood class (Table 2.1-1) and number of ducklings were also recorded during brood surveys. Habitat data collected was similar to that recorded during spring data collection. The eclipse plumage of drakes of many duck species and the cryptic nature of hens with broods limited the success of species and sex identification from helicopters in some cases. However, information collected was suitably robust to allow for an estimate of productivity and to identify important breeding locations.

**Table 2.1-1
Plumage Development of Young Waterfowl**

Class	Description
IA	Young are down-covered; 1 to 7 days of age
IB	Young are down-covered; 8 to 13 days of age
IC	Young are downed-covered, but colour faded, body elongated; 14 to 18 days of age
IIA	First feathers appear, replacing down on sides and tail; 19 to 27 days of age
IIB	Over half of body covered with feathers; 28 to 42 days of age
IIC	Small amount of down remains, among feathers of back; 28 to 42 days of age
III	Fully feathered but incapable of flight; 43 to 55 days of age, flying at 56 to 60 days of age

Reference: Bellrose (1980).

2.2 Results

Avian species observed were classified as dabblers, divers, geese, swans, waterbirds (including loons and grebes), shorebirds, and other (including raptors, gulls and terns) and analyzed as groups where appropriate. Harlequin ducks were analyzed separately to provide additional detail on this species. Species observed are listed in Table 2.2-1. A bird species list for the Schaft Creek study area is provided in Appendix 2. Detailed waterfowl and riverine bird survey data area provided in Appendix 3 and Appendix 4.

2.2.1 Waterfowl

A total of 21 species of waterfowl were observed within the study area, including six dabbling species, nine species of diver, two species of geese, two species of loons, trumpeter swans (*Cygnus buccinator*), and eared grebes (*Podiceps nigricollis*).

2.2.1.1 Spring Waterfowl Pair Survey

The spring waterfowl survey was conducted on May 2, 4 and 18, 2006, and included 14.0 hrs of aerial survey time. Overall, 1,727 birds of 27 species (Table 2.2-1) were observed to be associated with rivers and wetlands within the study area. The majority of the birds were waterfowl (Table 2.2-2): 65% were dabbling ducks (predominantly mallard [*Anas platyrhynchos*], green-winged teal [*Anas crecca*], and American wigeon [*Anas Americana*]), and 19% were diving waterfowl (mostly Barrow's goldeneye [*Bucephala islandica*], bufflehead [*Bucephala albeola*], and harlequin duck). The distribution of waterfowl was relatively uniform among reaches, although higher concentrations existed, particularly within the larger wetland complexes associated with Schaft Creek and Upper Mess Creek (Plate 2.2-1; Figure 2.2-1).

An estimate of density along reaches within the study area was also calculated for waterfowl (Table 2.2-2). The linear distance represented the area along the valley surveyed, and included wetlands within each drainage for waterfowl. The habitat use observed during spring surveys is summarized in Table 2.2-3. Generally, dabblers, swans, and geese were associated with more calm, low flowing water bodies such as marshes, ponds, and meandering river glides, while diving waterfowl exploited a wider range of habitats. Some diving species selected deep still water (e.g., lesser scaup [*Aythya affinis*] and ring-necked duck [*Athys collaris*]) while mergansers and goldeneye presence correlated with faster flowing riverine habitats. Shorebirds and other wading birds (predominantly American dipper [*Cinclus cinclus*]) were also associated with creek and river riffle habitat.

2.2.1.2 Summer Waterfowl Brood Survey

Summer brood surveys were conducted in conjunction with mountain ungulate surveys on July 17, 18, and 19, 2006, with an additional survey on August 14. Approximately 4.46 hours of aerial survey effort was completed for brood surveys. Overall, 408 birds of 22 species (Table 2.2-1) were documented in association with wetlands and streams during summer brood surveys in the study area. Broods of diving ducks, dabbling ducks, and geese were observed (Figure 2.2-2; Table 2.2-4), with most observations occurring during the last survey, August 14.

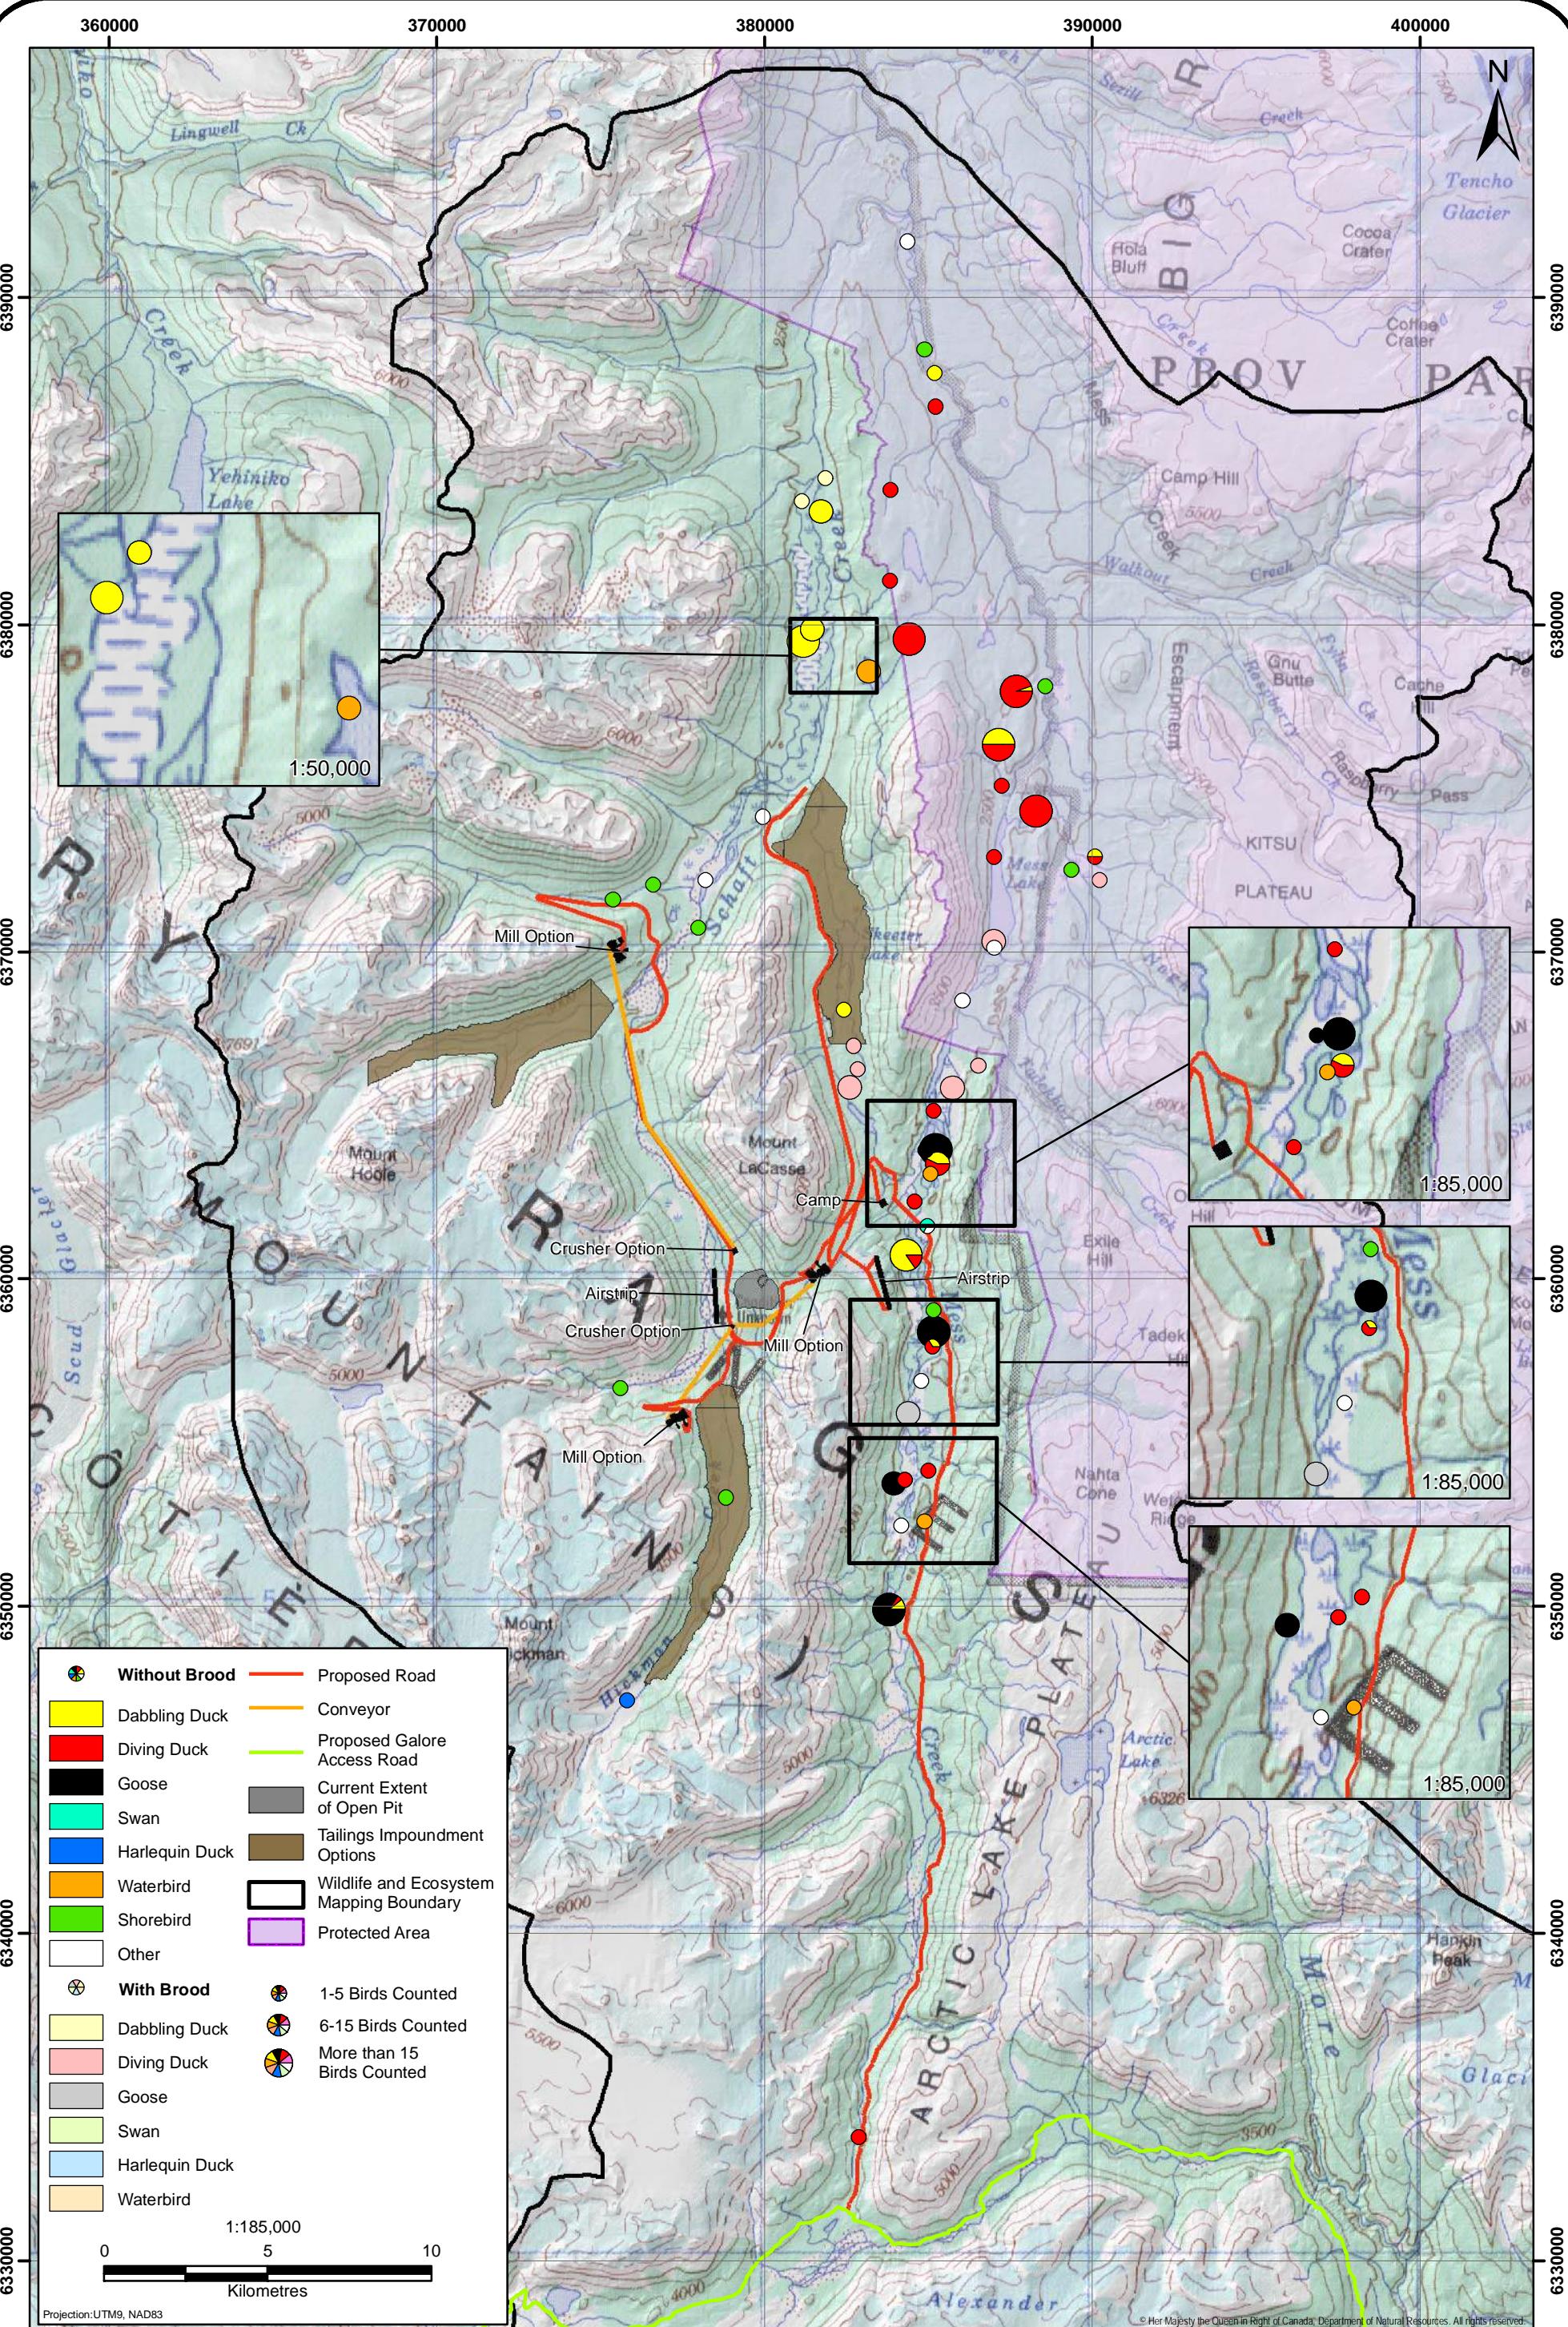

A total of 92 dabbling ducks were observed, with 4 mallard broods and 1 green-winged teal brood observed. During the July surveys, only one green-winged teal brood (class Ia) was encountered. Older classed (IIb to III) mallard broods were observed during the August survey.

There were 154 diving ducks observed during the survey including 16 broods produced by Barrow's goldeneye (7), lesser scaup (5), ring-necked duck (2), bufflehead (1), and an aggregation of 15 brood class III unidentified scoter (*Melanitta* spp.) species in Mess Lake. Nearly equal numbers of broods of diving ducks were encountered in July (7) and August (9), with July broods ranging from Ia to IIb, and the August ducklings developed to class III.

Table 2.2-4
**Summary of Waterfowl Brood Survey Results [Number of adults
 (number of broods, number of ducklings)]**

Reach	Dabblers	Divers	Geese	Swans	Loons	Shorebirds	Waterbirds	Other	Total

Note: Number of broods and/or ducklings included only when observed.

Waterfowl and Riverine Bird Summer Migration Survey Observations, 2006

Overall, 130 Canada geese (*Branta canadensis*) were observed (Plate 2.2-2); however, only one class I brood was noted. Typically, Canada geese nest early, and thus large flocks of moulting birds observed (up to 70) may have been well-developed young produced in 2006. A pair of trumpeter swans was also observed above Mess Lake in July, but no cygnets (*i.e.* juvenile swans) were detected. Both common (*Gavia immer*) and red-throated loons (*Gavia stellata*) and eared grebes were observed during the surveys. However, no direct evidence of breeding (*i.e.*, brood sightings) by these species was identified.

Plate 2.2-2. Flock of Canada Geese observed during August 2006.

The distribution of waterfowl brood observations was relatively similar among four sections of the study area. The lakes and wetlands of Schaft Creek to Hickman Creek supported 3 broods, lower Mess Creek supported 6 broods, upper Mess Creek supported 6 broods, and the tributaries supported 7 broods. Upper Mess Creek supported broods of divers, dabblers, and geese. Other areas supported broods of dabblers (Schaft Creek), divers (tributaries), or both (lower Mess Creek).

2.2.2 Harlequin Ducks and Riverine Bird

Harlequin ducks plus an additional five species of riverine bird or shorebird were observed within the study area including American dipper, common snipe (*Gallinago gallinago*), greater yellowlegs (*Tringa melanoleuca*), killdeer (*Charadrius vociferous*), and solitary sandpiper (*Tringa solitaria*). The following section focuses on harlequin duck.

2.2.2.1 Spring Harlequin Pair Survey

Harlequin duck pair surveys were conducted on May 2, 4, and 18, 2006. A total of 28 individuals were observed, which included 13 pairs (*i.e.* only 2 individuals were unpaired). The majority of observations were made within tributaries to the main stem of Schaft and Mess creeks (19 individuals) (Figure 2.2-1). Twenty-one of the 28 observations were made on May 18 along reaches that had been covered with snow and ice during the May 2 and 4 surveys. This suggests that the late spring may have delayed arrival, pairing, and breeding within the study area.

During the pair surveys, only riffle habitat on creeks and rivers (classified as RI-rf or CR-rf), supported harlequin ducks (Plate 2.2-3); of this, 18 of the observations were made in creeks while 10 of the observations were made in rivers. Observations were not made in middle Mess Creek along the access corridor, as much of this habitat consisted of deep, meandering glides and wetlands not typically used by harlequin ducks. Much of the upper Mess Creek was similar in topography to mid Schaft, supporting large areas of shallow, braided riffle, with little riparian habitat suitable for harlequin nesting structures.

Plate 2.2-3. Occupied harlequin duck habitat, tributary of Mess Creek, May 18, 2006.

Observations of harlequin duck densities per km of surveyed reach indicated that the tributaries of the Schaft and Mess Creek system supported higher densities of harlequins (0.28 ducks/km) than the Schaft/Hickman mainstem (0.12 ducks/km), lower Mess Creek (0.07 ducks/km), or upper Mess Creek (0.00 ducks/km). The forested riparian habitat combined with the stream geomorphology of the tributaries likely provided habitat more conducive to harlequin breeding,

and thus these reaches were selected in spring. An average density of 0.15 ducks/km was observed over the entire search area during the spring survey.

The American dipper was the only riverine bird identified during surveys. Of the 73 observations of American dipper, all were on riffle habitat, with 19 associated with riffles on creeks and 54 were within rivers. Shorebirds identified during surveys included greater yellowlegs, killdeer, Wilson's (common) snipe, and unidentified sandpipers (likely solitary and spotted). Shorebirds encountered were distributed within a variety of habitats; sandpiper species and killdeer were associated with river and creek riffles, greater yellowlegs were observed in marshes and bogs, and the Wilson's snipe encountered was flushed from a bog. The observed density of riverine and shorebirds was 0.75 bird/km along lower Mess Creek, 0.53 birds/km along upper Mess Creek, 0.84 birds/km along the Schaft and Hickman creeks, and 0.19 birds/km along tributaries associated with the Schaft and Mess drainage.

2.2.2.2 Summer Harlequin Brood Survey

Only one pair of harlequin ducks were encountered at the headwaters of Hickman Creek during the summer surveys (Figure 2.2-2). No harlequin broods were observed. A noted absence of harlequin duck production was also experienced in other watersheds locally (Rescan Environmental Services, *unpublished data*). There were very few observations of shorebirds during summer surveys, with 7 shorebirds of at least 3 species (greater yellowlegs, solitary sandpiper, and unidentified sandpipers), and 2 American dippers recorded. Therefore, no detailed analysis of habitat use or brood production by harlequin ducks or shorebirds was attempted at this stage.

2.2.2.3 Other Birds

In addition to waterfowl and riverine birds, eight other species of birds were incidentally observed during spring and/or summer aerial surveys including:

- American kestrel (*Falco sparverius*);
- bald eagle (*Haliaeetus leucocephalus*);
- belted kingfisher (*Ceryle alcyon*);
- golden eagle (*Aquila chrysaetos*);
- northern harrier (*Circus cyaneus*);
- osprey (*Pandion haliaetus*);
- red-tailed hawk (*Buteo jamaicensis*); and
- sharp-shinned hawk (*Accipiter striatus*).

An unidentified tern, likely an Arctic tern (*Sterna paradisaea*), was also observed during the summer brood surveys. Two ospreys were observed, including one juvenile. A bald eagle nest with three eggs was observed within a cottonwood tree near a wetland along Schaft Creek on May 4, 2006. A grizzly bear (*Ursus arctos*) with two cubs was observed in the Schaft Creek area on July 18.

2.3 Discussion

2.3.1 Waterfowl

There are many waterfowl species using the study area for various activities during the spring and summer months. Substantial numbers and a high diversity of waterfowl use the wetlands and streams associated with lower Schaft Creek and mid-Mess Creek south of Mess Lake. A large number of waterfowl were also observed to use these areas as staging habitats during spring migration, and waterfowl production was also encountered within these areas during summer. The large wetland complexes associated with the mid reach of Mess Creek to approximately the latitude of Arctic Lake, and the lower-mid reach of Schaft Creek to the latitude of Skeeter Lake were of the greatest importance for staging waterfowl in the study area.

While productivity in 2006 was less than anticipated, the weather experienced in 2006 may have influenced this to some extent. A number of locations within the study area support habitat suitable for breeding by a wide variety of waterfowl species. Most species of waterfowl identified breed in nests constructed along the edges of water bodies. However, many species, such as bufflehead, hooded mergansers (*Lophodytes cucullatus*), and goldeneyes nest in naturally formed or woodpecker excavated tree cavities. Cavity-nesting waterfowl species may therefore breed in treed areas near the water, but may also breed up to 800 m from the water in forested habitat (Pierre *et al.*, 2001). Cavity-nesting waterfowl require habitat with sufficiently old forest with trees of a large diameter (usually softened by fungal degradation), and woodpecker activity within 1 km of water bodies. The presence of cavity nesting waterfowl and cavity nesting raptors such as American kestrel (observed incidentally) also suggests an importance of nearby old forest capable of hosting large nest cavities.

2.3.2 Harlequin Ducks and Riverine Birds

The important reaches for harlequin duck pairs (in spring) were within the secondary tributaries associated with both the Schaft and Mess Creek watersheds. The area of upper Schaft Creek (below Hickman Creek) and the area associated with Mess Creek appear to have a combination of geomorphology and riparian habitat that do not support harlequin duck breeding; however, these sites may occasionally be used by harlequin duck pairs moving upstream, or when maturing broods are heading back to the ocean in late summer. The apparent lack of productivity by this species in areas where pair activity was observed (*e.g.* no broods detected during surveys), may be a product of the late spring in 2006, combined with the cryptic nature of the young broods, than a lack of use of this habitat for breeding.

Noise disturbance from aerial surveys is also known to cause avoidance behaviour in harlequin ducks (Goudie, 2006), and these effects may be exacerbated when adults have young to protect, or if young react more strongly to overhead noise. Therefore ground surveys for detecting broods of this species may be more effective than overhead flights in the future. Far fewer hours of flight were also invested in finding broods, relative to the number of hours spent conducting spring pair surveys, and so proportionally fewer brood observations were expected for all groups. Observations from other projects (*e.g.* Freeman and Goudie, 1996; Freeman and Goudie, 2001), suggest that harlequin ducks nest near areas of pair activity, and as such, the reaches in the study

area where pairs were observed are likely to be important for nesting and brood rearing by harlequin ducks.

The observed density of harlequin ducks within the Schaft Creek study area (0.15 harlequin ducks/km) was three fold the observed density of the neighbouring Galore Creek study area (0.05 duck/km; Rescan Environmental Services, 2006), suggesting the Schaft Creek area may be of greater overall regional value to this species.

Other riverine birds and shorebirds were distributed based on their habitat preference. Shore birds, including greater yellowlegs and Wilson's snipe, were associated with still water and larger marsh complexes in mid reaches while sandpipers and American dippers were most commonly associated with stream riffle habitat. No exceptional observations or observations of wading bird species at risk were made during the harlequin surveys.

2.3.3 Other Birds

The observation of a bald eagle nest and young osprey suggest that a suitable prey base exists to support breeding by these species. Osprey feed almost exclusively on fish, suggesting that fish resources in or near to the area can support osprey populations. Bald eagles feed on fish, small mammals, and other alternate prey sources such as waterfowl, which were all present near the bald eagle nest.

3. RAPTORS

3. Raptors

Raptors were highlighted as a group requiring enhanced consideration in the area for the Project by the Cassiar-Iskut Stikine Land and Resource Management Plan (CIS LRMP; BC MSRM, 2000) and regulating agencies. Raptor surveys were conducted in 2006 to assess the presence and distribution of focal raptor species, and to identify nest locations that may be impacted by the development of the proposed access corridor and mine site. Focal species included:

- Bald eagle;
- Gyrfalcon;
- Peregrine falcon;
- Northern goshawk; and
- Short-eared owl (*Asio flammeus*).

3.1 Methods

Raptor survey methods used call playback surveys for northern goshawk and stand watches for tree and cliff nesting raptors. All incidental observations of raptors or raptor nests were noted and geo-referenced in conjunction with other field inventories conducted in the study area.

3.1.1 Call Playback Survey

During the breeding season, many birds use species-specific calls and songs to establish and defend territories, to attract mates, and to communicate with young. Using pre-recorded calls or call playbacks to simulate the presence of an "intruder" in an already claimed territory elicits a defensive response in the target species. The response of the bird, whether it is a close approach, accompanied by an aggressive behaviour, or a distant vocalization, allows the observer to record the presence of the species. Call playbacks are typically used for inconspicuous, scarce, or nocturnal species known to respond to calls during the breeding season, such as the northern goshawk. Surveys for northern goshawks were therefore conducted using call paybacks along the proposed access corridor and within the mine site footprint in June 2006. The call playback survey (CPS) methodology adhered to RISC standards (BC MSRM, 2001).

Calls of northern goshawks were played at all call playback stations using a RadioShack® loudspeaker linked to a RadioShack® digital recorder with a mono cable. The equipment used was tested prior to and throughout the surveys, to ensure that the volume required was adequate. When batteries were fully charged, the equipment was found to be loud enough to elicit responses from goshawks in the desired vicinity of the playback.

The CPS for northern goshawk was conducted in conjunction with variable radius point counts (VRPC) for breeding songbirds (Section 4.1.1) at VRPC locations where suitable goshawk habitat (*i.e.*, mature coniferous forest) was present. Thus, a similar amount of survey days were excluded due to poor weather from both survey types. CPS were conducted within three hours of sunrise. In general, a VRPC would be performed at a survey station, observers would then wait for two minutes, and then perform a CPS at the same station. Because the broadcast area

for the call playbacks was greater than the 200 m distance between each VRPC station, CPS were often conducted at every second or third VRPC station rather than at every site to avoid recording the presence of the same bird among adjacent sites. Northern goshawk begging calls were played during CPS.

During surveys, one person played the recorded call for 35 seconds, and an observer listened for 60 seconds, followed by another 35 second period of call playbacks. This procedure was repeated two more times, with a final 60 seconds of silent observation after the third round of recorded calls. As each round of calls was played, the direction of the loudspeaker was rotated 360 degrees such that the entire range around the focal playback location was included. All wildlife observations during these surveys were recorded, as many other species of songbirds will “mob” a perceived predator, and other species of raptors may behave aggressively to other raptorial species within their breeding territories.

3.1.2 Stand Watch Survey

Tree Nesting Raptors

Surveys for tree nesting raptors were conducted using stand watch techniques in riparian habitat along the major rivers of the access corridor. Surveys were conducted in mid-June, 2006. Particular emphasis was placed on detecting bald eagles and locating nests. Survey sites were initially chosen following aerial reconnaissance of riparian habitat. Once sites with potentially suitable habitat were located two surveyors would land and position themselves with binoculars and high-powered spotting scopes at vantage points where the habitat could be monitored for activity. One to three hours were spent observing for raptors at each site. Ground surveys were supplemented with incidental aerial observations in riparian habitat throughout the survey period.

Cliff Nesting Raptors

Surveys for cliff nesting raptors using stand watch techniques were conducted adjacent to suitable nesting habitat along the access corridor. Surveys were conducted in mid-June, 2006. Suitable nesting habitat was initially identified following aerial reconnaissance. Once sites with suitable habitat were located and deemed accessible, two surveyors would land and position themselves with binoculars and high-powered spotting scopes at vantage points where cliffs could be monitored for activity. Surveyors also scanned cliffs for white-wash and/or the presence of *Xanthoria* spp., an orange lichen that is often abundant near nest or roost sites where bird droppings accumulate. Approximately one to three hours were spent searching for raptors at each site. Ground surveys were supplemented with an aerial survey in areas of raptor activity or to confirm the presence of nests.

3.2 Results

Nine raptor species were identified from the CPS and stand watches as well as from incidental observations during other surveys (*i.e.*, waterfowl and songbird surveys) (Table 3.2-1). In addition, the rusty blackbird (*Euphagus carolinus*), a provincially blue-listed and COSEWIC ranked species of concern, was also identified during both the CPS and stand watch surveys.

Table 3.2-1
Raptor Species Encountered during Avian Surveys

Species	Call Playback Survey	Stand Watch Survey	Incidental Observation*
American kestrel	-	-	Y
Bald eagle	-	-	Y
Golden eagle	-	-	Y
Merlin	-	-	Y
Northern Goshawk	Y	-	-
Northern harrier	-	-	Y
Osprey	-	Y	Y
Red-tailed hawk	-	-	Y
Sharp-shinned hawk	-	-	Y

*includes observations made during waterfowl surveys and the variable radius point count surveys.

3.2.1 Call Playback Survey

Between June 15 and 20, 2006, 24 call playback plots were completed within the study area (Figure 3.2-1), for a total of 120 minutes of call playback effort. One northern goshawk was identified along Mess Creek (approximately 130 m south of plot SG1). This bird called three times before flying towards the river in a south westerly direction. Observers believed that this individual was unlikely to be of the *laingi* subspecies, and therefore not a species at risk. A mobbing response from a rusty blackbird was encountered along Mess Creek (plot SG2). Detailed survey data for call playback surveys are provided in Appendix 5.

3.2.2 Stand Watch Survey

Between June 15 and 21, 2006, nine stand watch locations were surveyed for tree and cliff nesting raptors (Figure 3.2-1) over a period of 645 minutes. Detailed survey data for raptors are provided in Appendix 6. The only raptor species encountered during stand watch surveys was osprey, with five observations. Observations included three active nests along Mess Creek (Plate 3.2-1), as well as nesting activity near watch site SSW1.

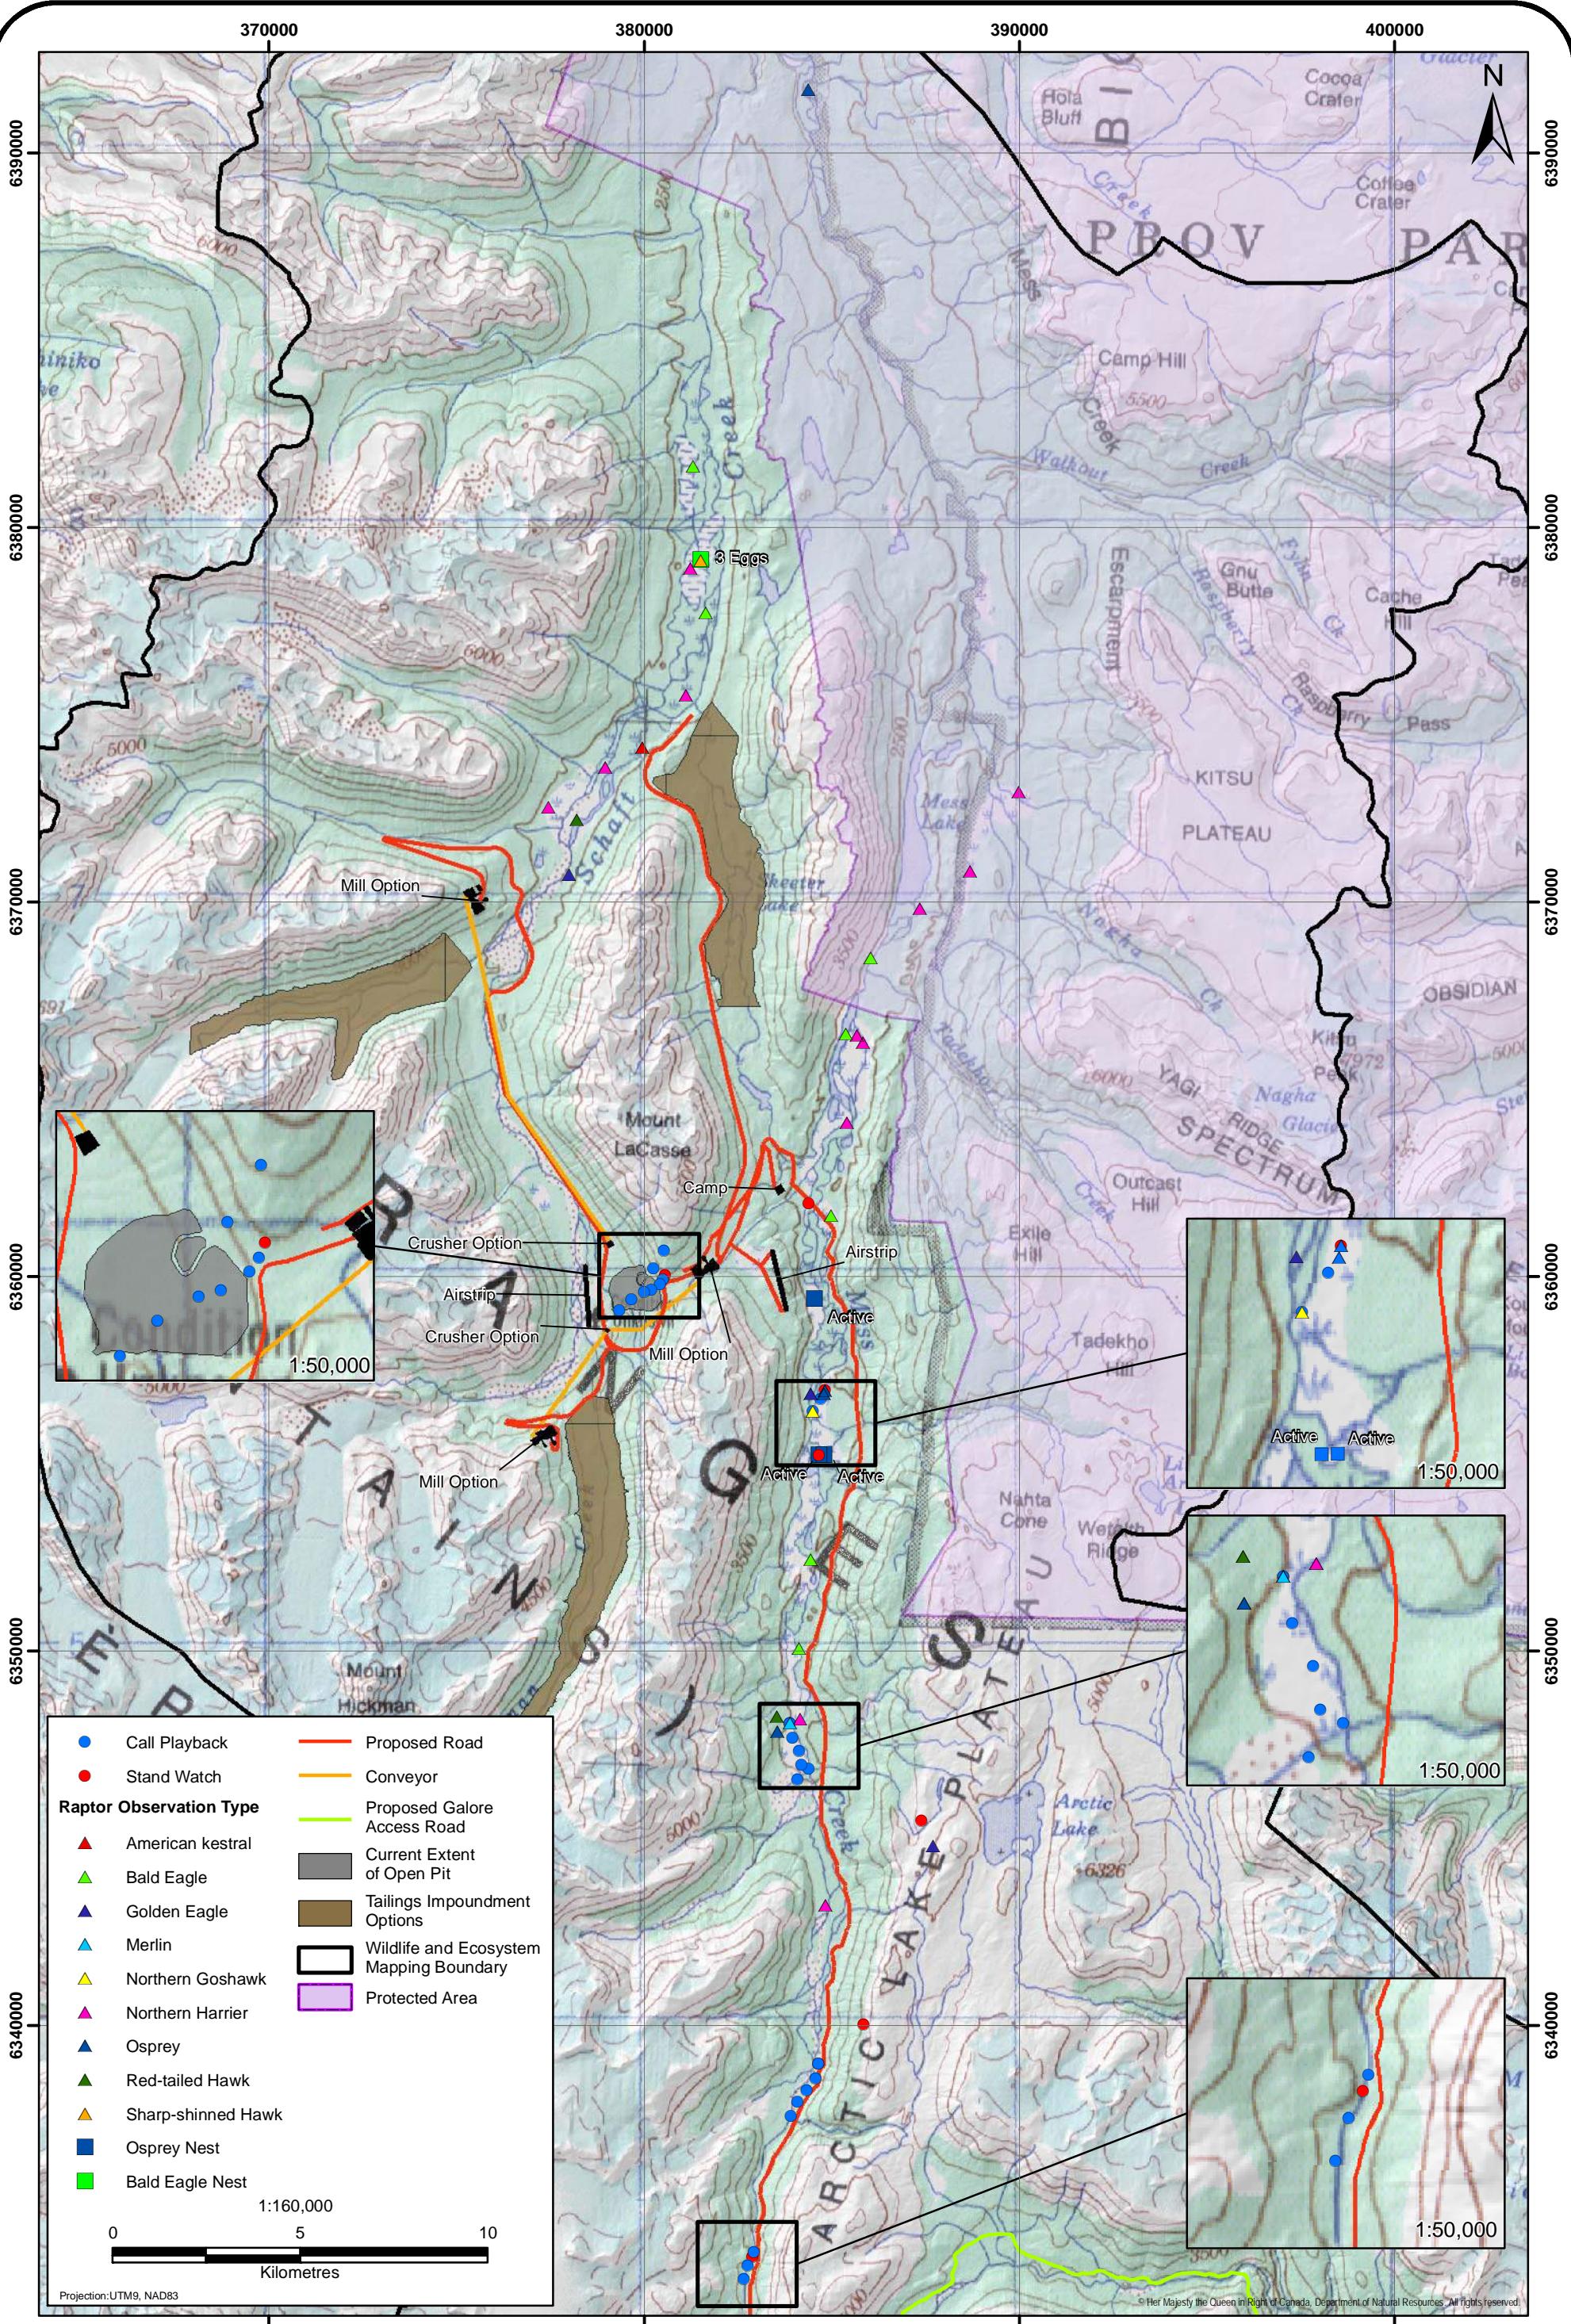

Plate 3.2-1. Location of two active osprey nests along Mess Creek, June 2006.

3.3 Discussion

Osprey and northern goshawk, were detected during stand watch and call playback surveys. Seven additional raptor species were also encountered during other components of the bird inventory work. No observations of cliff dwelling species at risk (gyrfalcon and peregrine falcon) were made, and three incidental observations of a golden eagle were noted.

The only riparian associated raptor species encountered during the stand watch surveys was osprey, which were observed to nest within the study area. As aforementioned in the waterfowl survey section, bald eagles were also identified incidentally and a nest was noted along Schaft Creek. Therefore, the study area is used by raptors; however, numbers and species diversity did not appear to be unique or high regionally. While northern goshawk are relatively resilient to stand level habitat changes (Mahon and Doyle, 2005), osprey are affected by alterations to riparian habitats, and by toxins in their dietary fish which can cause nesting failure (*e.g.* DesGranges *et al.*, 1998; Elliot *et al.*, 2005). The presence of young osprey may be a good indicator of ecosystem health, and that relatively uncontaminated fish populations and riparian habitat exist at present in the area. The rusty blackbird, another riparian dwelling bird and a species of concern, was also incidentally observed during raptor surveys. As the rusty blackbird was detected again in VRPC songbird surveys, the presence of this species of concern is further discussed in Section 4.

**Raptor Survey Locations, Observations
and Incidental Sightings, 2006**

4. BREEDING SONGBIRDS

4. Breeding Songbirds

A diverse community of forest and alpine birds is anticipated to breed within the Schaft Creek study area. Each species potentially exploits different habitat and has unique sensitivities to development. To effectively assess impacts of the proposed development to breeding avifauna, particularly those identified at risk, characterizing the community through field inventory was required.

4.1 Methods

Field surveys for breeding songbirds were conducted along the proposed access road and within the potential mine site area using one survey methodology: variable radius point counts (VRPC). Surveys focused on sites within 500 m of the proposed access road and mine site footprint and were stratified by habitat type within each BEC zone.

4.1.1 Variable Radius Point Count Surveys

Variable radius point counts (VRPC) were conducted during the 2006 breeding season to characterize songbird diversity and to allow for the detection of focal species in each of the main habitat types along the proposed transportation corridor and mine site. VRPC focused on characterizing songbirds, as this group is relatively territorial and detectable and is the most diverse vertebrate group, and thus a good indicator of how diverse an area is. In north-western British Columbia, the breeding period extends from early June to the first week of July, with slight annual fluctuation due to local climatic conditions. VRPC in the study area were conducted in two phases with lower elevation areas surveyed in early June and higher elevation areas surveyed in late June. All surveys were conducted by a very experienced observer following RISC standards (RIC, 1999b).

Songbird activity during the breeding season, particularly territorial vocalizations, peak in intensity and frequency one hour before and after sunrise. Due to logistical and safety concerns associated with helicopter access, however, it was not possible to travel to sites until approximately 30 minutes before local sunrise. Thus, VRPC typically commenced within one hour of local sunrise, and were completed each day within four hours of local sunrise.

The intensity of songbird territorial vocalizations can be affected by local weather conditions. On days with high winds, extreme temperatures, or heavy precipitation, territorial activities in songbirds decreases. In addition, the ability of the observer to accurately detect avian species decreases in very poor weather. VRPC were therefore only conducted as weather permitted, with surveys suspended or cancelled when wind speeds exceeded a Beaufort class 3, or precipitation exceeded the “light rain” class (RIC, 1999b).

The initial location of the VRPC conducted each day was selected from the set of habitat types as randomly as possible. However, locations chosen were constrained by logistical and safety concerns (*e.g.*, helicopter accessibility, presence of grizzly bears). Survey sites were geo-referenced using a hand-held Garmin 76 GPS. Before starting a survey, the observers remained silent for several minutes to allow birds affected by their arrival to return to normal activity. The

VRPC survey then commenced and continued for five minutes. All avian species were recorded by species name. The estimated horizontal distance from the observer to the bird was recorded. Vegetation characteristics were recorded as required. All points and bird observations were recorded with GPS.

Upon completion of each survey, the predetermined direction of travel was checked with a compass, and the observers walked in that direction for a minimum of 200 m before commencing the next VRPC survey. Observers continued to survey until the direction of travel was blocked, surveys had to be terminated due to poor weather, or the four hour period after local sunrise had passed.

4.1.2 Analysis of Breeding Songbird Surveys

Songbird observations were downloaded from GPS recording devices and compiled with ArcView 3.2. Observations were described for each of the major ecosystems occurring within the study area associated with 500 m from the access road and the mine infrastructure. This included BAFAunp, and ESSFmc BEC zones. BEC classification was consistent with a 1:20,000 scale provincial coverage; however, these classifications may be further modified after ground evaluation associated with the 2007 TEM mapping effort is completed.

4.2 Results

Spring songbird surveys were conducted during seven mornings, between June 15 and 21, 2006, within the Schaft Creek study area. Surveys were conducted in the two dominant BEC subzones (ESSFmc and BAFAunp) within the study area and focused on the areas anticipated to be influenced by development including the access corridor (Figure 4.2-1). Detailed survey data for VRPC are provided in Appendix 7.

A total of 61 species were detected during 70 VRPCs, including the provincially blue-listed and COSEWIC ranked species of concern rusty blackbird (Table 4.2-1). There were 10 species observed in the BAFAun and 56 in the ESSFmc. Within the BAFAun BEC zone two nests were detected during the VRPC survey including one of a horned lark, and one of an American pipit. No nests were detected in the ESSFmc; however, one sooty grouse female was incidentally observed sitting on 5 eggs within the ESSFmc along upper Mess Creek during raptor stand watch surveys (Plate 4.2-1).

The number of birds and species observed varied considerably among survey plots (Figure 4.2-2). The highest species diversity and abundance of birds was found along upper Mess Creek (plots SS1, SS2 and SS3) adjacent to the proposed access corridor. This habitat is transitional between forest and marshland, and natural edges between contrasting habitat types are often important areas of high species diversity. VRPC plots with no birds detected were associated with higher elevation rocky sites devoid of trees (*i.e.*, plots SS56 and SS57). Low bird diversity and abundance tended to be associated with rocky habitat above the treeline (*e.g.*, plots SS29, SS58, SS65, SS62, SS34, SS30, and SS32).

(a) Bird Species Abundance

Plate 4.2-1. Sooty grouse on 5 eggs, June 18, 2006.

4.3 Discussion

There was a moderately diverse community of breeding birds identified within the Schaft Creek study area, with a high level of variation among VRPC plots surveyed. It should be noted that because only two BECs subzones were represented in VRPC surveys, the likelihood of observing certain species within lower elevations or alternate ecosystems was limited. Of the species observed, the rusty blackbird was the only species at risk identified, which is provincially blue listed as a COSEWIC species of concern. Beyond this, no notable or unexpected species observations were made. The number of species identified (61) in the study area examined here was similar to the number identified in the adjacent Galore Creek from VRPC surveys in 2005/2006 (Rescan Environment Service, 2006), suggesting these study areas are similarly important for maintaining the species diversity of terrestrial avifauna in the region.

Species richness and number of detections varied considerably between VRPC plots within the study area, which allows for a limited extrapolation of habitat characteristics associated with high and low species diversity. Songbird diversity and abundance in other studies tend to correlate positively with increased vegetative diversity and structural heterogeneity (*e.g.* vertical stratification of vegetation; Whelan, 2001), wide forested buffer areas along water or where two habitat types transition (Peak and Thompson, 2006), and/or the availability of diverse food resources (Whelan, 2001). From preliminary analyses, it appears that the VRPC plots that hosted the highest songbird abundance and diversity were also located in the most productive

habitat surveyed (lowest elevation) near a transition between low-elevation forest and riparian marshland habitat. Inversely, higher elevation rocky habitat hosted the lowest diversity and abundance of songbirds.

One species of concern, the rusty blackbird, was detected during songbird surveys, as well as during incidental observations made during raptor surveys. Rusty blackbirds have declined by approximately 90% over the past 3 decades, which has earned them a status as a COSEWIC species of concern (Greenberg and Droege, 1999). Rusty blackbirds select riparian habitat with a relatively high density and diversity of plant species along creeks, rivers, and lakes in order to breed (Larue *et al.* 1995). Thus, the presence of this species in the creekside vegetation along upper Mess Creek suggests that the riparian forest in that area may host a relatively high level of riparian vegetative density and diversity. Interestingly, the rusty blackbird observation coincides with the area that hosted the highest diversity and abundance of other songbird species (*i.e.*, 703 m elevation marshland/forest transition near plots SS1-SS4), making this a habitat of particular importance for maintaining local avian diversity.

APPENDIX 1

LIST OF BIRD SPECIES OF CONSERVATION CONCERN FOR

THE SCHAFT CREEK PROJECT

Appendix 1
List of Bird Species of Conservation Concern for the Schaft Creek Project

Bird Species	Scientific Name	Provincial Status	COSEWIC Listing	Information Source	Probability of Occurrence	Rationale for Consideration
American bittern	<i>Botaurus lentiginosus</i>	Blue	Not listed	C	Possible	Unknown distribution and inventory in study area, suitable wetland nesting habitat available.
Bald eagle	<i>Haliaeetus leucocephalus</i>	Yellow	Not at risk	D	Confirmed	Multiple observations during waterfowl aerial surveys within the Schaft Creek area during field surveys in 2006.
California gull	<i>Larus californicus</i>	Blue	Not listed	F	Possible	Observed in Spatsizi Plateau Wilderness Park. Breeds in the Okanagan therefore likely transient, not a management concern within the study area.
Great blue heron	<i>Ardea herodias fannini</i>	Blue	Special Concern	C	Possible	Outside of distribution, but inventory data lacking and high quality riparian with mature forest may provide opportunity for a rookery. A record identified near Telegraph Creek. Andre Breault of Environment Canada suggest there may be a possibility of occurrence.
Gyrfalcon	<i>Falco rusticolus</i>	Blue	Not at risk	C,D, F	Possible	Within published nesting distribution. Reliance on cliffs and ledges, habitat within study area. All fledged by late July. Identified in Mt. Edziza Provincial Park and Stikine River Provincial Park including a breeding record in July.
Harlequin duck	<i>Histrionicus histrionicus</i>	Yellow	Not listed	E	Confirmed	Highlighted by Canadian Wildlife Service (CWS) as a species requiring increased consideration. High quality breeding habitat exists in study area. 2006 Field surveys confirmed presence.
Hudsonian godwit	<i>Limosa haemastica</i>	Red	Not listed	C, D	Very Unlikely	Included do to lack of inventory data only. Available sedge meadow BAFA habitat may be insufficient to support breeding population.
Le Conte's sparrow	<i>Ammodramus leconteii</i>	Blue	Not listed	F	Unknown	Observed in Spatsizi Plateau Wilderness Park. This species breeds in the extreme north east of the province. As such, the observation in the region is likely transient and not associated with a breeding population. While suitable habitat consisting of marsh land, wetlands, flooded areas exist within the study area, it is unlikely this species breeds in the study area and therefore does not warrant further management consideration.
Lesser (American) golden plover	<i>Pluvialis dominica</i>	Blue	Not listed	C, D	Unlikely	Only known breeding population in B.C. identified near the upper Stikine, BAFA habitat; however, there may have been an account 600 km south as well. Habitat selected includes short grass areas, burned agricultural lands, grassy lake shores, golf courses. May not be sufficient habitat in study area, although rocky/sandy areas with suitable vegetation may be used.
Long-tailed duck	<i>Clangula hyemalis</i>	Blue	Not listed	C,D,F,G	Unknown	Just outside distribution, but no inventory. Nest in BAFA, near suitable lakes. Potential habitat in study area. Identified in Mount Edziza Provincial Park. Andre Berault of EC suggests that this species may occur, but difficult to inventory. Identified in the Stikine/Iskut by Simpson and Bianchinin (1997).
Northern goshawk	<i>Accipiter gentilis laingi</i>	Red	Threatened	B, D, G	Unlikely	Habitat along the most western edge of the study area may support this subspecies, but more likely to harbour subspecies of goshawk not at risk. Identification of the difference between this subspecies and subspecies less at risk may prove difficult without taking DNA samples.
Peregrine falcon	<i>Falco peregrinus anatum, F.p.pealei</i>	Red/blue	Threatened Schedule 1 SARA / Special Concern	C,D,F	Possible	Limited inventory, possible breeding distribution identified to the north and south of study area. Nesting habitat in cliffs and ledges. Fledging estimated mid-July. Identified in Mount Edziza Provincial Park. Both subspecies may exist in study area.
Red-necked phalarope	<i>Phalaropus lobatus</i>	Blue	Not listed	C, F	Possible	Observed in Mount Edziza and Spatsizi Plateau Wilderness Parks, but occurrence may be migratory. Potential to occur in study area is dependant on availability of suitable low vegetation, wet sub-alpine meadows, however breeding range is believed to be farther north. Likely not a management concern within the study area.

Appendix 1
List of Bird Species of Conservation Concern for the Schaft Creek Project (completed)

Bird Species	Scientific Name	Provincial Status	COSEWIC Listing	Information Source	Probability of Occurrence	Rationale for Consideration
Rusty blackbird	<i>Euphagus carolinus</i>	Blue	Special Concern	A	Possible	Very little know about this species, study area well into published breeding distribution.
Sandhill crane	<i>Grus canadensis</i>	Blue	Not listed	C, H	Possible	Potentially within nesting range, suitable habitat of sufficient size may not be available. Should be able to identify with waterfowl surveys. May stop over, not observed to date, but observation noted near lower Iskut. Possibly used for breeding (a few pairs maximum), directed management likely not required as habitat should be conserved via other initiatives. Sandhill crane may also nest in forested areas and lead broods to wetlands.
Short-billed dowitcher	<i>Limnodromus griseus</i>	Blue	Not listed	C, D	Unlikely	Suggested breeding range may include Spatsizi Plateau Wilderness Park, but quality habitat may be insufficient in study area.
Short-eared owl	<i>Asio flammeus</i>	Blue	Special Concern	F, D	Very Possible	Observed in Spatsizi Plateau Wilderness Park. Insufficient distribution data for breeding, however suitable habitat represented to the east of the study area.
Smith's longspur	<i>Calcarius pictus</i>	Blue	Not listed	C, F	Possible	Potential distribution identified to mid-Stikine. Nests alpine/tree line open grassy, shrubby, sub alpine valley bottoms and mountain passes. Breeding accounts documented in Spatsizi Plateau Wilderness Park and Mount Edziza Provincial Park. Birds of BC vol 2 suggest that NBM ecoprovince has the greatest concentration in summer compared to the remainder of the province and notes that a careful nest search has not been completed near the Spatsizi. Breeding habitat has been described as high elevation open shrub/sedge habitats as high as 2700 m.
Surf Scoter	<i>Melanitta perspicillata</i>	Blue	Not listed	C, F	Unknown	Nesting populations in freshwater lakes to the east of study area, no inventory within. Potential presence dependant on availability of suitable lakes in study area. Identified in Mount Edziza Provincial Park. Andre Berault of EC suggests that this species may occur, but difficult to inventory.
Trumpeter swan	<i>Cygnus buccinator</i>	Blue	Not at risk	D	Confirmed	Identified in the Cassiar Iskut-Stikine Land and Resource Management Plan (CIS LRMP), and highlighted by Canadian Wildlife Service (CWS) as a species requiring increased consideration. Presence of this species was confirmed through field surveys. Breeding population likely; however, not confirmed by these surveys. Population is likely Pacific, no winter use observed during 2005 moose surveys, but early spring use observed in March.
Upland sandpiper	<i>Bartramia longicauda</i>	Red	Not listed	F, D	Possible	Observed in Spatsizi Plateau Provincial Park. Breeds farther north therefore likely transient, not a management concern within the study area.
Wandering tattler	<i>Heteroscelus incanus</i>	Blue	Not listed	C, F, D	Possible	Study area just south west of published distribution (Dease Lake), breeding habitat includes remote and rugged habitat with mountain streams. Nests on gravel bars associated with mountain streams up to BAFA BEC. Abundant habitat available in study area, may combine search with aquatic inventory. Observed in Mount Edziza and Spatsizi Plateau Wilderness Parks.
